## Adversarial Search (Game Playing)

Chapter 6

#### Outline

- $\Diamond$  Games
- $\Diamond$  Perfect play (minimax)
- $\Diamond \quad \alpha \beta \text{ pruning}$
- ♦ Resource limits and approximate evaluation
- $\Diamond$  Games of chance
- ♦ Games of imperfect information

#### Games vs. search problems

"Unpredictable" opponent  $\Rightarrow$  solution is a strategy specifying a move for every possible opponent reply

Time limits  $\Rightarrow$  unlikely to find goal, must approximate

#### Plan of attack:

- Computer considers possible lines of play (Babbage, 1846)
- Algorithm for perfect play (Zermelo, 1912; Von Neumann, 1944)
- Finite horizon, approximate evaluation (Zuse, 1945; Wiener, 1948; Shannon, 1950)
- First chess program (Turing, 1951)
- Machine learning to improve evaluation accuracy (Samuel, 1952–57)
- Pruning to allow deeper search (McCarthy, 1956)

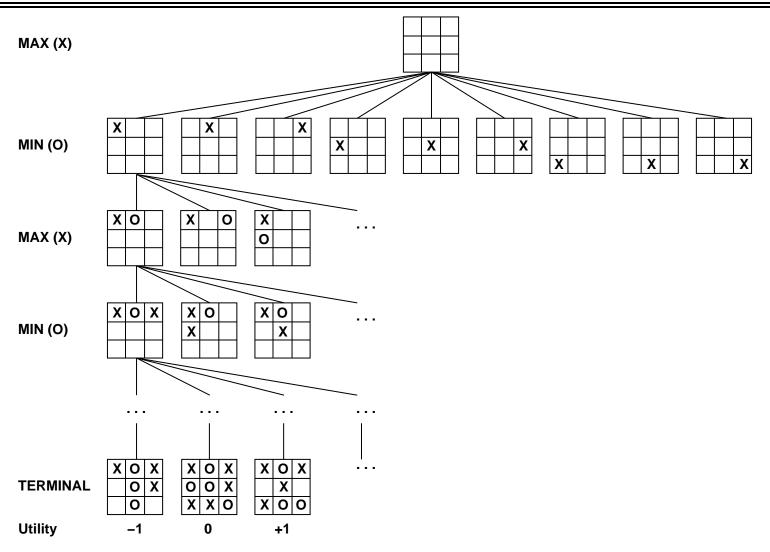

# Types of games

perfect information

imperfect information

deterministic	chance
chess, checkers,	backgammon
go, othello	monopoly
battleships,	bridge, poker, scrabble
blind tictactoe	nuclear war

# Game tree (2-player, deterministic, turns)

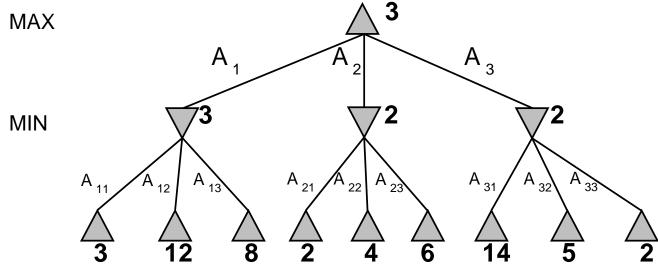

#### Minimax

Perfect play for deterministic, perfect-information games

Idea: choose move to position with highest minimax value

= best achievable payoff against best play

### Minimax algorithm

```
function MINIMAX-DECISION(state) returns an action
   inputs: state, current state in game
   return the a in ACTIONS(state) maximizing MIN-VALUE(RESULT(a, state))
function Max-Value(state) returns a utility value
   if TERMINAL-TEST(state) then return UTILITY(state)
   v \leftarrow -\infty
   for a, s in Successors(state) do v \leftarrow \text{Max}(v, \text{Min-Value}(s))
   return v
function Min-Value(state) returns a utility value
   if TERMINAL-TEST(state) then return UTILITY(state)
   v \leftarrow \infty
   for a, s in Successors(state) do v \leftarrow \text{Min}(v, \text{Max-Value}(s))
   return v
```

Complete??

Complete?? Yes, if tree is finite (chess has specific rules for this)

Optimal??

Complete?? Yes, if tree is finite (chess has specific rules for this)

Optimal?? Yes, against an optimal opponent. Otherwise??

Time complexity??

Complete?? Yes, if tree is finite (chess has specific rules for this)

Optimal?? Yes, against an optimal opponent. Otherwise??

Time complexity??  $O(b^m)$ 

Space complexity??

Complete?? Yes, if tree is finite (chess has specific rules for this)

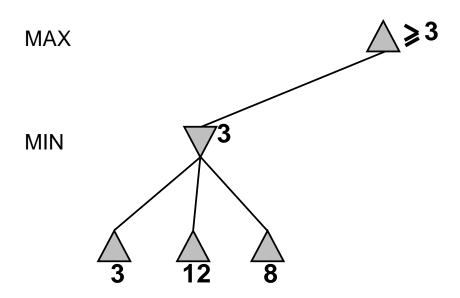

Optimal?? Yes, against an optimal opponent. Otherwise??

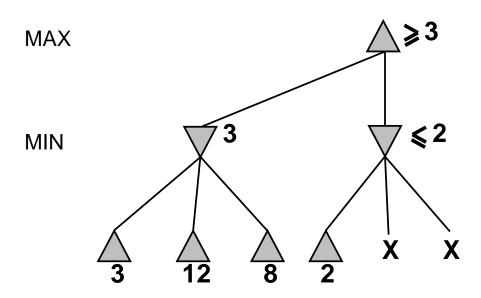

Time complexity??  $O(b^m)$ 

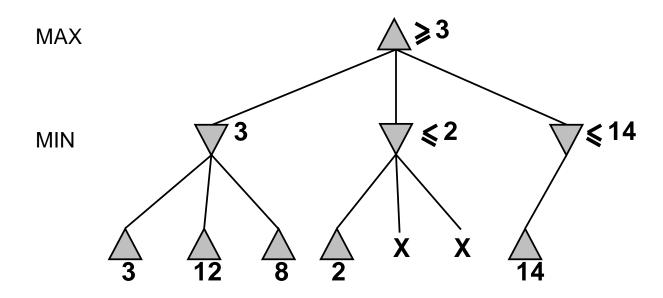

Space complexity?? O(bm) (depth-first exploration)

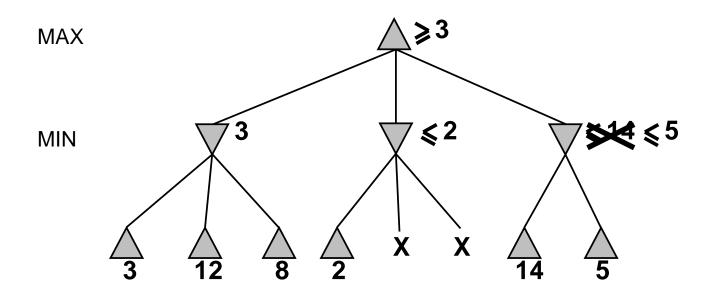

For chess,  $b \approx 35$ ,  $m \approx 100$  for "reasonable" games  $\Rightarrow$  exact solution completely infeasible

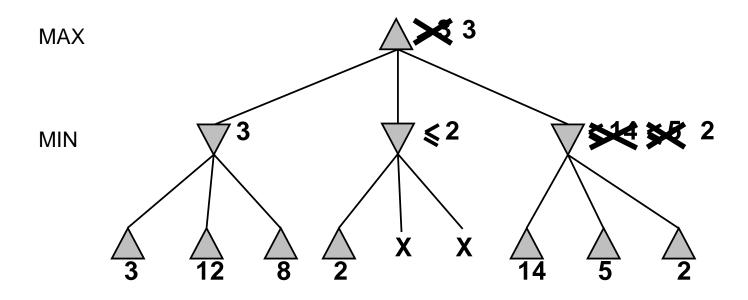

But do we need to explore every path?

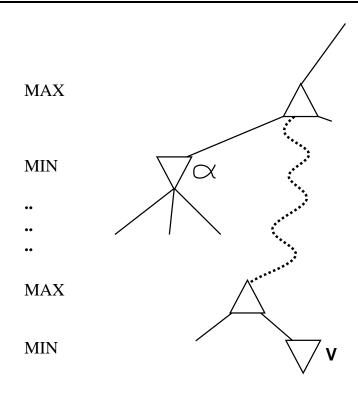

### Why is it called $\alpha-\beta$ ?

 $\alpha$  is the best value (to MAX) found so far off the current path If V is worse than  $\alpha$ , MAX will avoid it  $\Rightarrow$  prune that branch Define  $\beta$  similarly for MIN

#### The $\alpha$ - $\beta$ algorithm

```
function ALPHA-BETA-DECISION(state) returns an action
   return the a in ACTIONS(state) maximizing MIN-VALUE(RESULT(a, state))
function Max-Value(state, \alpha, \beta) returns a utility value
   inputs: state, current state in game
             \alpha, the value of the best alternative for MAX along the path to state
             eta, the value of the best alternative for \ _{
m MIN} along the path to state
   if TERMINAL-TEST(state) then return UTILITY(state)
   v \leftarrow -\infty
   for a, s in Successors(state) do
      v \leftarrow \text{Max}(v, \text{Min-Value}(s, \alpha, \beta))
      if v \geq \beta then return v
      \alpha \leftarrow \text{Max}(\alpha, v)
   return v
```

function MIN-VALUE( $state, \alpha, \beta$ ) returns a  $utility\ value$  same as MAX-VALUE but with roles of  $\alpha, \beta$  reversed

#### Properties of $\alpha$ - $\beta$

Pruning does not affect final result

Good move ordering improves effectiveness of pruning

With "perfect ordering," time complexity =  $O(b^{m/2})$ 

- ⇒ *doubles* depth of search
- $\Rightarrow$  can easily reach depth 8 and play good chess

A simple example of the value of reasoning about which computations are relevant

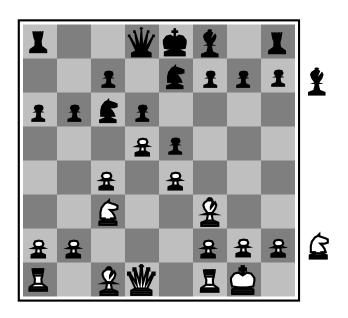

### Resource limits

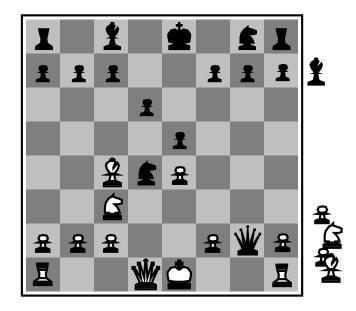

Suppose we have 100 seconds, explore  $10^4$  nodes/second  $\Rightarrow 10^6$  nodes per move

#### Standard approach:

- cutoff test
  - e.g., depth limit (perhaps add quiescence search)
- evaluation function
  - = estimated desirability of position

#### **Evaluation functions**

Black to move

White slightly better

White to move

**Black winning** 

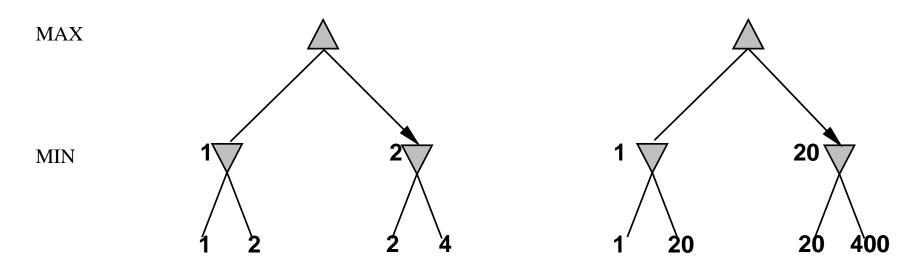

For chess, typically *linear* weighted sum of features

$$Eval(s) = w_1 f_1(s) + w_2 f_2(s) + \ldots + w_n f_n(s)$$

e.g., 
$$w_1 = 9$$
 with

 $f_1(s) =$  (number of white queens) – (number of black queens), etc.

#### Digression: Exact values don't matter

Behaviour is preserved under any  $\emph{monotonic}$  transformation of Eval

Only the order matters:

payoff in deterministic games acts as an ordinal utility function

#### Cutting off search

MINIMAXCUTOFF is identical to MINIMAXVALUE except

- 1. TERMINAL? is replaced by CUTOFF?
- 2. Utility is replaced by EVAL

Does it work in practice?

$$b^m = 10^6, \quad b = 35 \quad \Rightarrow \quad m = 4$$

4-ply lookahead is a hopeless chess player!

4-ply  $\approx$  human novice 8-ply  $\approx$  typical PC, human master 12-ply  $\approx$  Deep Blue, Kasparov

### Deterministic games in practice

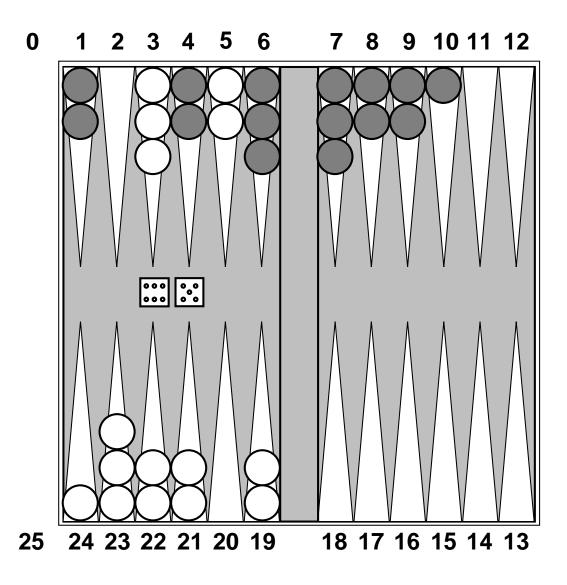

Checkers: Chinook ended 40-year-reign of human world champion Marion Tinsley in 1994. Used an endgame database defining perfect play for all positions involving 8 or fewer pieces on the board, a total of 443,748,401,247 positions.

Chess: Deep Blue defeated human world champion Gary Kasparov in a six-game match in 1997. Deep Blue searches 200 million positions per second, uses very sophisticated evaluation, and undisclosed methods for extending some lines of search up to 40 ply.

Othello: human champions refuse to compete against computers, who are too good.

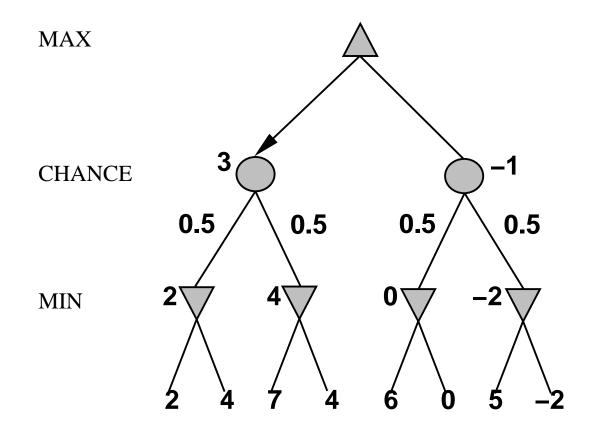

Go: human champions refuse to compete against computers, who are too bad. In go, b>300, so most programs use pattern knowledge bases to suggest plausible moves.

## Nondeterministic games: backgammon

### Nondeterministic games in general

In nondeterministic games, chance introduced by dice, card-shuffling Simplified example with coin-flipping:

#### Algorithm for nondeterministic games

EXPECTIMINIMAX gives perfect play

Just like MINIMAX, except we must also handle chance nodes:

. . .

if state is a MAX node then

return the highest ExpectiMinimax-Value of Successors(state)

if state is a MIN node then

return the lowest ExpectiMinimax-Value of Successors(state)

if *state* is a chance node then

return average of EXPECTIMINIMAX-VALUE of SUCCESSORS(state)

. . .

#### Nondeterministic games in practice

Dice rolls increase b: 21 possible rolls with 2 dice Backgammon  $\approx$  20 legal moves (can be 6,000 with 1-1 roll)

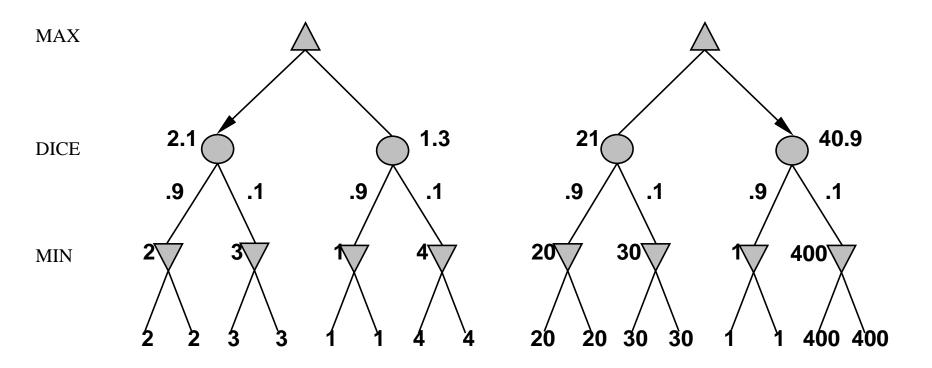

depth 
$$4 = 20 \times (21 \times 20)^3 \approx 1.2 \times 10^9$$

As depth increases, probability of reaching a given node shrinks  $\Rightarrow$  value of lookahead is diminished

 $\alpha$ – $\beta$  pruning is much less effective

TDGAMMON uses depth-2 search + very good EVAL  $\approx$  world-champion level

### Digression: Exact values DO matter

Behaviour is preserved only by *positive linear* transformation of  $\mathrm{EVAL}$ 

Hence EVAL should be proportional to the expected payoff

### Games of imperfect information

E.g., card games, where opponent's initial cards are unknown

Typically we can calculate a probability for each possible deal

Seems just like having one big dice roll at the beginning of the game\*

Idea: compute the minimax value of each action in each deal, then choose the action with highest expected value over all deals\*

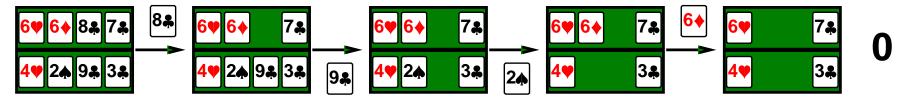

Special case: if an action is optimal for all deals, it's optimal.\*

GIB, current best bridge program, approximates this idea by

- 1) generating 100 deals consistent with bidding information
- 2) picking the action that wins most tricks on average

### Example

Four-card bridge/whist/hearts hand, MAX to play first

### Example

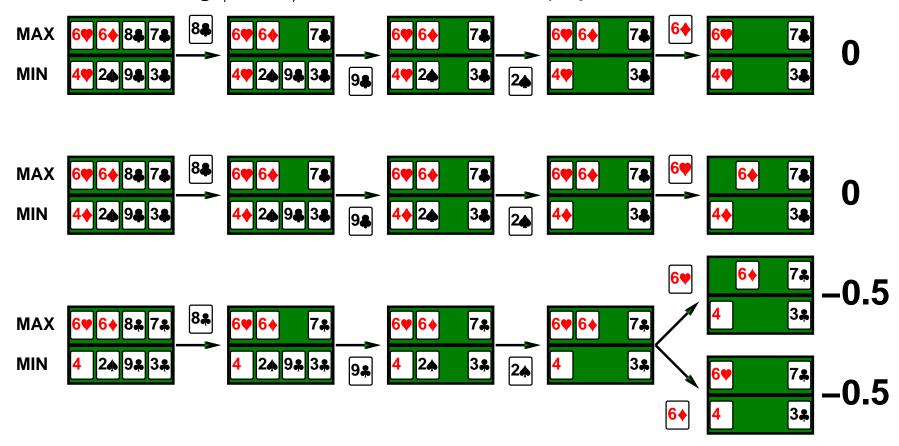

Four-card bridge/whist/hearts hand, MAX to play first

### Example

Four-card bridge/whist/hearts hand, MAX to play first

#### Commonsense example

Road A leads to a small heap of gold pieces

Road B leads to a fork:

take the left fork and you'll find a mound of jewels; take the right fork and you'll be run over by a bus.

#### Commonsense example

Road A leads to a small heap of gold pieces

Road B leads to a fork:

take the left fork and you'll find a mound of jewels; take the right fork and you'll be run over by a bus.

Road A leads to a small heap of gold pieces

Road B leads to a fork:

take the left fork and you'll be run over by a bus; take the right fork and you'll find a mound of jewels.

#### Commonsense example

Road A leads to a small heap of gold pieces

Road B leads to a fork:

take the left fork and you'll find a mound of jewels; take the right fork and you'll be run over by a bus.

Road A leads to a small heap of gold pieces

Road B leads to a fork:

take the left fork and you'll be run over by a bus; take the right fork and you'll find a mound of jewels.

Road A leads to a small heap of gold pieces

Road B leads to a fork:

guess correctly and you'll find a mound of jewels; guess incorrectly and you'll be run over by a bus.

#### Proper analysis

\* Intuition that the value of an action is the average of its values in all actual states is WRONG

With partial observability, value of an action depends on the information state or belief state the agent is in

Can generate and search a tree of information states

Leads to rational behaviors such as

- ♦ Acting to obtain information
- ♦ Signalling to one's partner
- $\diamondsuit$  Acting randomly to minimize information disclosure
